Went up the “Climb Above Dribbles” gully today. In general the gully is in good shape- not too much faceting below the October crust, scoured in some areas, 30cm wind slabs in others that were well bonded. We did observe debris from a size 1.5 windslab that most likely failed during Friday/Saturday wind and snow event. Got a decent look into the terrain above treeline, no avalanche activity observed aside from what looked like a broken cornice. No wet loose activity observed today although the snow surface was wet and air temps felt above 45 F.
